

Statistics 520 - Assignment 3

Sam Olson

Assignment 3

1. **(10 pt.)** Suppose that a random variable Y has a beta distribution with parameters α and β . A standard form for the probability density function of Y is, for $\alpha > 0$ and $\beta > 0$,

$$f(y \mid \alpha, \beta) = \frac{\Gamma(\alpha + \beta)}{\Gamma(\alpha)\Gamma(\beta)} y^{\alpha-1} (1-y)^{\beta-1}, \quad 0 < y < 1.$$

Put this density in canonical exponential family form.

Using properties of exponential families, find $E\{\log(Y)\}$ and $E\{\log(1-Y)\}$ expressed in terms of the original α and β parameters.

Note: Use $\Gamma'(x)$ to denote the derivative of the gamma function,

$$\frac{d}{dx} \Gamma(x).$$

Answer

The canonical exponential family form of the density is:

$$f(y \mid \alpha, \beta) = \exp\{(\alpha - 1) \log(y) + (\beta - 1) \log(1 - y) + \log\left(\frac{\Gamma(\alpha + \beta)}{\Gamma(\alpha)\Gamma(\beta)}\right)\} \mathbb{I}[y \in (0, 1)]$$

Where:

$$\theta_1 = \alpha - 1, \quad \theta_2 = \beta - 1.$$

$$T = (T_1, T_2) \text{ for } T_1(y) = \log(y), \quad T_2(y) = \log(1 - y).$$

$$B(\theta) = -\log\left(\frac{\Gamma(\alpha + \beta)}{\Gamma(\alpha)\Gamma(\beta)}\right) = \log \Gamma(\alpha) + \log \Gamma(\beta) - \log \Gamma(\alpha + \beta).$$

$$c(y) = \mathbb{I}[y \in (0, 1)], \text{ where } \mathbb{I} \text{ denotes the indicator function}$$

Note: Though $B(\theta)$ is as given above, a simplified version which makes taking partial derivatives easier is the equivalent form:

Using properties of exponential families, and noting that the natural parameters (θ_1, θ_2) are linearly related to the parameters (α, β) :

$$\begin{aligned} E\{\log(Y)\} &= E\{T_1(Y)\} = \frac{\partial}{\partial \theta_1} B(\theta) = \frac{\partial}{\partial \alpha} (\log \Gamma(\alpha) + \log \Gamma(\beta) - \log \Gamma(\alpha + \beta)) \\ &= \frac{\Gamma'(\alpha)}{\Gamma(\alpha)} - \frac{\Gamma'(\alpha + \beta)}{\Gamma(\alpha + \beta)} \end{aligned}$$

And

$$\begin{aligned} E\{\log(1 - Y)\} &= E\{T_2(Y)\} = \frac{\partial}{\partial \theta_2} B(\theta) = \frac{\partial}{\partial \beta} (\log \Gamma(\alpha) + \log \Gamma(\beta) - \log \Gamma(\alpha + \beta)) \\ &= \frac{\Gamma'(\beta)}{\Gamma(\beta)} - \frac{\Gamma'(\alpha + \beta)}{\Gamma(\alpha + \beta)} \end{aligned}$$

2. **(5 pt.)** Suppose that a random variable Y has a Poisson distribution with parameter λ .
A standard form for the probability mass function of Y is, for $\lambda > 0$,

$$f(y \mid \lambda) = \frac{1}{y!} \lambda^y \exp(-\lambda), \quad y = 0, 1, 2, \dots$$

Put this probability mass function in canonical exponential family form.

Using properties of exponential families, verify that $E(Y) = \lambda$.

Answer

The canonical exponential family form of the density is:

$$f(y \mid \lambda) = \exp\{y \log(\lambda) - \lambda - \log(y!)\}$$

$$\theta_1 = \log(\lambda).$$

$$T_1(y) = y.$$

$$B(\theta) = \exp(\theta_1).$$

$$c(y) = -\log(y!)$$

Using properties of exponential families, and noting the natural parameter θ_1 is non-linearly related to the parameter λ :

$$E\{T_1(Y)\} = \frac{\partial}{\partial \theta_1} B(\theta) = \frac{\partial}{\partial \theta_1} e^{\theta_1} = e^{\log(\lambda)} = \lambda$$

3. Suppose that a random variable Y has a gamma distribution with parameters α and β .
A standard form for the probability density function of Y is, for $\alpha > 0$ and $\beta > 0$,

$$f(y | \alpha, \beta) = \frac{\beta^\alpha}{\Gamma(\alpha)} y^{\alpha-1} \exp(-\beta y), \quad y > 0.$$

Note: You may have seen a gamma density written with a parameter that is equal to $1/\beta$ in the above expression. Use the parameterization given above to answer this question (I think it will be easier).

(a) (5 pts.) Write the gamma density in the form of a two-parameter exponential family. Using properties of exponential families, derive the expected values of Y and $\log(Y)$.

(b) (5 pts.) Write the gamma density in the form of an exponential dispersion family with parameters θ and ϕ . Derive the expected value of Y .

Answer

(a)

The gamma density in the form of a (canonical) two-parameter exponential family is of the form:

$$f(y | \alpha, \beta) = \exp\{(\alpha - 1) \log(y) - \beta y + \alpha \log(\beta) - \log \Gamma(\alpha)\} \mathbb{I}[y > 0]$$

Where:

$$\theta_1 = \alpha - 1 \quad \theta_2 = -\beta,$$

$$T = (T_1(y), T_2(y)), \quad T_1(y) = \log(y), \quad T_2(y) = y,$$

$$B(\theta) = \log \Gamma(\alpha) - \alpha \log(\beta)$$

And

$c(y) = \mathbb{I}[y > 0]$, where \mathbb{I} denotes the indicator function

Using properties of exponential families, and noting the natural parameters (θ_1, θ_2) are linear functions of the parameters (α, β) , then:

$$E(\log(Y)) = E\{T_1(Y)\} = \frac{\partial}{\partial \theta_1} B(\theta) = \frac{\partial}{\partial \alpha} (\log \Gamma(\alpha) - \alpha \log(\beta)) = \frac{\Gamma'(\alpha)}{\Gamma(\alpha)} - \log(\beta)$$

(Another Digamma function, in the flesh!)

Also:

$$E(Y) = E\{T_2(Y)\} = \frac{\partial}{\partial \theta_2} B(\theta) = \frac{\partial}{\partial (-\beta)} (\log \Gamma(\alpha) - \alpha \log(\beta)) = \frac{\alpha}{\beta}$$

(b)

Now, taking the canonical form, we may then write the exponential dispersion family form as:

$$\begin{aligned} f(y | \alpha, \beta) &= \exp\left((\alpha - 1) \log y - \beta y + \alpha \log \beta - \log \Gamma(\alpha)\right) \\ &= \exp\left\{\alpha \left(\log\left(\frac{\beta}{\alpha}\right) - y \frac{\beta}{\alpha}\right) + ((\alpha - 1) \log y + \alpha \log \alpha - \log \Gamma(\alpha))\right\} \\ &= \exp\{\phi(y\theta - b(\theta)) + c(y, \phi)\}, \quad y > 0, \end{aligned}$$

where

$$\phi = \alpha, \quad \theta = -\frac{\beta}{\alpha}$$

And

$$b(\theta) = -\log(-\theta), \quad \text{and } c(y, \phi) = (\alpha - 1) \log y + \alpha \log \alpha - \log \Gamma(\alpha)$$

Using the properties of an exponential dispersion family, we may calculate expectation via:

$$E(Y) = \frac{d}{d\theta} b(\theta) = \frac{d}{d\theta} (-\log(-\theta)) = -\frac{1}{\theta} = \frac{\alpha}{\beta}$$
