

1. (a) (i) For all $x \neq 0, 1$, $X_n(x) = 0$ for large n , and $P(\{0, 1\}) = 0$. This proves $X_n \rightarrow X$ almost surely (P) as $n \rightarrow \infty$.
(ii) Since for fixed $T > 0$, $\int |X_n| I_{\{|X_n| > T\}} dP = n \cdot m([0, \frac{1}{n}] \cup [1 - \frac{1}{n}, 1]) = n \cdot \frac{2}{n} = 2$, $\forall n > T$, $\{X_n\}$ is not UI.
(iii) Here $E|X_n - X| = E(X_n) = n \cdot \frac{2}{n} = 2$ for all n large, so X_n does not converge to X in L^1 .
(b) If $\{X_n^p\}$ is UI, and the measure is finite (which is the case in the example above), then $X_n \rightarrow X$ a.e. (P) would imply $X_n \rightarrow X$ in L^p for $p \geq 1$ (HW problem: 2.36(b)). There are other correct answers too, for example, along the lines of DCT.
2. (a) $\mu_3(\emptyset) = 3\mu_1(\emptyset) + 2\mu_2(\emptyset) = 0$; and $\mu_3(A) = 3\mu_1(A) + 2\mu_2(A) \geq 0 \Rightarrow \mu_3(A) \in [0, \infty]$, $\forall A \in \mathcal{F}$; If $\{A_i\}$ is a disjoint collection of sets in $\mathcal{F}$, then $\mu_3(\cup_i A_i) = 3\mu_1(\cup_i A_i) + 2\mu_2(\cup_i A_i) = 3\sum_i \mu_1(A_i) + 2\sum_i \mu_2(A_i) = \sum_i (3\mu_1(A_i) + 2\mu_2(A_i)) = \sum_i \mu_3(A_i)$.
So μ_3 is a measure.
(b) $\nu(A) = 0 \Rightarrow \mu_1(A) = \mu_2(A) = 0 \Rightarrow \mu_3(A) = 3\mu_1(A) + 2\mu_2(A) = 0$. So $\mu_3 \ll \nu$.
Will show: $\frac{d\mu_3}{d\nu} = 3\frac{d\mu_1}{d\nu} + 2\frac{d\mu_2}{d\nu}$ a.e. (ν). Since $\mu_1 \ll \nu$ and $\mu_2 \ll \nu$, then $\exists f_1, f_2 \geq 0$ s.t. $\mu_1(A) = \int_A f_1 d\nu$, $\mu_2(A) = \int_A f_2 d\nu$. By definition, $\mu_3(A) = 3\mu_1(A) + 2\mu_2(A) = 3\int_A f_1 d\nu + 2\int_A f_2 d\nu = \int_A (3f_1 + 2f_2) d\nu$ by linearity of integrals. Hence by uniqueness of RN derivatives, $\frac{d\mu_3}{d\nu} = 3f_1 + 2f_2 = 3\frac{d\mu_1}{d\nu} + 2\frac{d\mu_2}{d\nu}$ a.e. (ν).
(c) Let $B = \mathbb{N} \cup \{0\} = \mathbb{N}_0$, then $2\mu_2(B^c) = 0 = \nu(B)$, i.e. $2\mu_2 \perp \nu$. Choose $\mu_s = 2\mu_2$, $\mu_a = 3\mu_1$, then $\mu = \mu_a + \mu_s$. To show $\mu_a \ll \nu$ and compute $\frac{d\mu_a}{d\nu}$.
Note that if $\phi_{2,3}$ represent the density of $Normal(2, 3)$, then by definition $\mu_1(A) = \int_A \phi_{2,3} dm$ and $\nu = m$. So, $\frac{d\mu_1}{d\nu} = \phi_{2,3}$ from RN theorem. Hence, from the proposition in the text, $\frac{d\mu_a}{d\nu} = \frac{d(3\mu_1)}{d\nu} = 3\frac{d\mu_1}{d\nu} = 3\phi_{2,3}$.
3. (a) Let $\phi(x) = -\log x$, $x > 1$, then $\phi(x)$ is a convex function.
If $EX < \infty$, then since $0 \leq \log x \leq x$, $\forall x \geq 1$, we have $0 \leq E(\log X) \leq EX$, i.e. $E \log X < \infty$. By Jensen's inequality, $E\phi(X) \geq \phi(EX)$, i.e. $E(\log X) \leq \log(EX)$.
If $EX = \infty$, then $E \log X \leq \infty = \log(EX)$ holds trivially.
Hence $E(\log X) \leq \log(EX)$.
(b) Apply Cauchy-Schwarz to $ZI_{\{Z > 0\}}$ to obtain
$$E[ZI_{\{Z > 0\}}] \leq [E(Z^2)]^{1/2} [P(Z > 0)]^{1/2}$$
using the fact that $I_{\{Z > 0\}}^2 = I_{\{Z > 0\}}$ and $E[I_{\{Z > 0\}}] = P(Z > 0)$. Also, since Z is nonnegative, $E(Z) = E(ZI_{\{Z=0\}}) + E(ZI_{\{Z > 0\}}) = E(ZI_{\{Z > 0\}})$. Hence, we get
$$[E(Z)]^2 \leq E(Z^2)P(Z > 0)$$
which gives the inequality. Note $[E(Z)]^2 \neq 0$ here since $Var(Z) > 0$.
